

BIOINFROMHER MODULE 2 PROJECT

Tracking the Evolution of the Hemoglobin Beta (HBB) Gene across Species

CONDUCTED BY :
Maram Nhaili

1 Sequence Retrieval and blast search:

1.1 Sequence Retrieval:

The screenshot displays the NCBI Gene page for HBB (hemoglobin subunit beta) [Homo sapiens (human)]. The page includes a summary section with details such as the official symbol (HBB), full name (hemoglobin subunit beta), primary source (HGNC:HGNC:4827), and gene type (protein coding). It also lists the RefSeq status (REVIEWED), organism (Homo sapiens), and lineage (Eukaryota, Metazoa, Chordata, Craniata, Vertebrata, Euteleostomi, Mammalia, Eutheria, Euarchontoglires, Primates, Haplorhini, Catarrhini, Hominidae, Homo). The summary also mentions that the alpha (HBA) and beta (HBB) loci determine the structure of the 2 types of polypeptide chains in adult hemoglobin, Hb A. The normal adult hemoglobin tetramer consists of two alpha chains and two beta chains. Mutant beta globin causes sickle cell anemia. Absence of beta chain causes beta-zero-thalassemia. Reduced amounts of detectable beta globin causes beta-plus-thalassemia. The order of the genes in the beta-globin cluster is 5'-epsilon -- gamma-G -- gamma-A -- delta -- beta-3'. [provided by RefSeq, Jul 2008]

The genomic context section shows the location (11p15.4) and exon count (3). A table of contents on the right lists various sections: Summary, Genomic context, Genomic regions, transcripts, and products, Expression, Bibliography, Phenotypes, Variation, HIV-1 interactions, Pathways from PubChem, Interactions, General gene information, Markers, Related pseudogene(s), Homology, Gene Ontology, General protein information, NCBI Reference Sequences (RefSeq), Related sequences, Additional links, and Locus-specific Databases.

The screenshot displays the NCBI Genomic regions, transcripts, and products page for HBB. The page shows a genomic track with various annotations, including the HBB gene structure, transcripts, and regulatory regions. The track is labeled with coordinates (5,227,200 to 5,228,400) and includes a search bar for the genomic sequence (NC_000011.10 Chromosome 11 Reference GRCh38 p14 Primary Assembly). The track shows the HBB gene structure with exons and introns, and various regulatory elements like enhancers and promoters. The page also includes a list of related resources on the right, such as BioAssay, by Gene target, BioAssays, RNAi Target, Tested, BioProjects, BioSystems, Books, CCDS, Conserved Domains, dbVar, Full text in PMC, Full text in PMC_nucleotide, Functional Class, GAP, Gene neighbors, Genome, GEO Profiles, GTR, MedGen, Nucleotide, OMIM, Protein, and PubChem Compound.

1.3 Blast search :

Species	Acession Number	Identity
Cow	M63453.1	81.09%
Mouse	EF605360	79.61%
Zebrafish		No significant similarity found
Chicken		No significant similarity found
Champanzee	X02345.1	98.71%

2 Pairwise sequence Alignment :

Species	Similarity	Identity	Number of gaps
Cow	8.9%	8.9%	89.1%
Champanzee	99%	99%	0%

Interpretation:

Based on the data provided from the table above we can confirm that the chimpanzee has more conserved regions than the cow because its similarity and identity (99%) is higher than the one found in the cow which represents 8.9%. Moreover, we can see that the number of gaps is higher in the cow than the chimpanzee.

3 Multiple sequence alignment:

Alignment with colours

The sequence logo shows that each columns correspond to a position in MSA (multiple sequence alignment).we observe high conserved regions due to the height of the nucleotide at each position where their total height correspond to 2 bits.

Additionally, there are highly conserved residues meaning there is little variation across sequences at those sites.

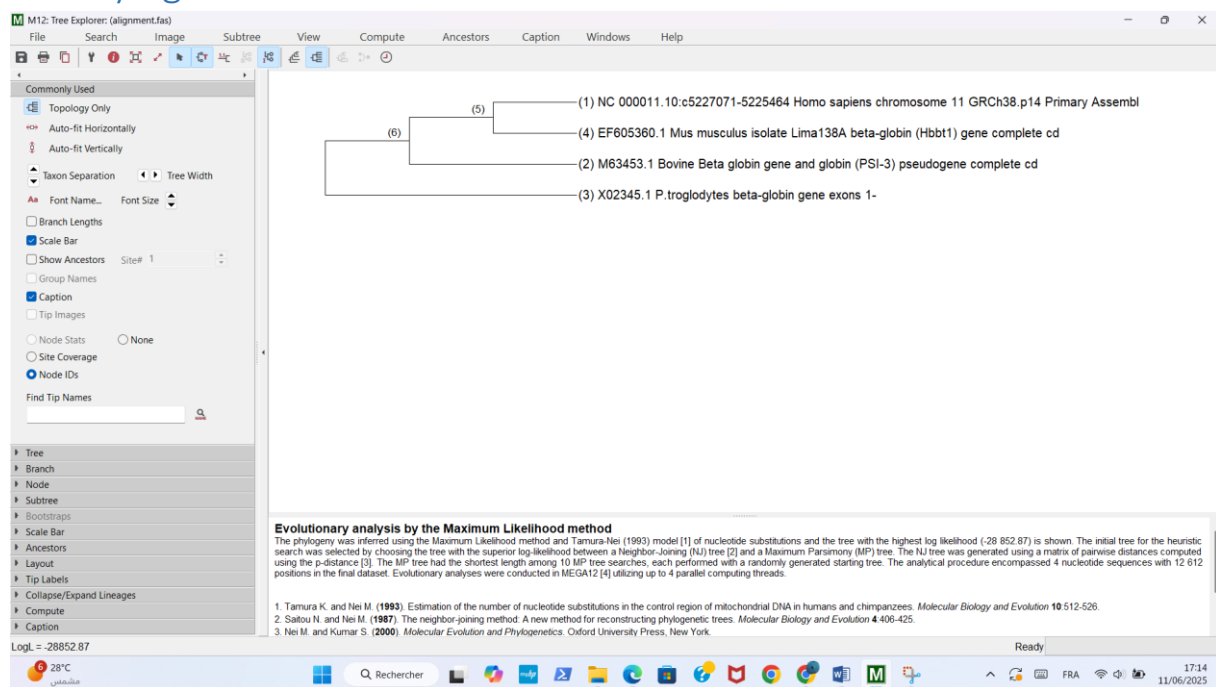

These conserved regions play critical role. They are functional importance where these regions could be :

- A promoter
- An enhancer
- A binding site for transcription factors or regulatory proteins

Structural stability

Evolutionary conservation

4 Phylogenetic tree construction:

- Human and Mouse beta-globin sequences cluster together more closely than with the other species, suggesting a more recent common ancestor between them for this gene region (which might reflect conserved functional regions rather than strict evolutionary distance).
- Chimpanzee (P. troglodytes) appears more distant, which is biologically unexpected given its close relation to humans. This suggests:

The chimpanzee sequence may be shorter (only "exons 1—"), or

There could be alignment gaps or divergence in the sequenced region used.

- Bovine (cow) gene shows greater divergence, as expected due to larger evolutionary distance from primates and rodents.

Does this tree match what you expect evolutionarily?

No, this tree does not match the expected evolutionary relationships of the species involved — especially not in the broad evolutionary sense.
